AIJ Technical Guide for Temporary Restoration of RC School Buildings Damaged by 921 Chichi Earthquake

by

Yoshiaki Nakano¹

ABSTRACT

An earthquake of a magnitude of 7.7 (USGS) occurred at 1:47 local time on September 21, 1999, with an epicenter near Chichi in the central part of the Republic of China (921 Taiwan Chichi Earthquake). This earthquake caused extensive damage to buildings and civil infrastructures, and more than 2,000 people were killed mainly due to devastating damage to reinforced concrete buildings.

Immediately after the earthquake, the Architectural Institute of Japan (AIJ) organized a reconnaissance team including the author based on the Agreement of Cooperation between Architectural Institute of the Republic of China (AIROC) and AIJ. They surveyed hardest-hit areas during October 13 through 21 under the cooperation of AIROC and recognized the urgency of cooperation on reconstruction of damaged communities. AIROC also requested technical cooperation for prompt recovery of damaged buildings, especially of low to medium-rise RC school buildings.

Following the request from AIROC, a second team to contribute to the prompt recovery from aftermath in the affected areas was again dispatched by AIJ during November 18 through 28, and proposed a technical guide applicable to RC school buildings in Taiwan through field surveys, several discussions and exchange of mutual knowledge and experiences.

In this paper, the outline of the AIJ technical guide for temporary restoration of RC school buildings damaged by 921 Chichi Earthquake is briefly presented.

INTRODUCTION

The 921 Taiwan Chichi Earthquake, which centered on the middle part of Taiwan, destroyed numerous buildings and facilities including low- to high-rise apartment houses, individual residences, school buildings, hospitals, public offices etc. Immediately after the event, the Architectural Institute of Japan (AIJ) dispatched the first reconnaissance team led by Prof. Akenori Shibata, Tohoku Bunka Gakuen University, to survey damaged areas.

After the earthquake, Architectural Institute of the Republic of China (AIROC) was in charge of reconstruction planning of school buildings. Although prompt recovery from the aftermath was most needed, rational guides on quantitative damage assessment, simplified seismic capacity evaluation procedures, decision criteria for repair, strengthening or demolition, and technical manuals for restoration were not available, and AIROC requested

Yoshiaki Nakano, Associate Professor, Institute of Industrial Science, the University of Tokyo

AIJ to cooperate on the restoration of damaged RC school buildings.

Following the request from AIROC, AIJ decided to dispatch an expert team on damage restoration. The team consisting of 6 members led by the author visited the damaged areas and discussed with researchers and structural engineers in Taiwan, and compiled a technical guide for temporary restoration which could be applied to damaged RC school buildings in Taiwan and held a technical seminar based on the guide.

OBJECTIVES AND SCOPE OF TEMPORARY RESTORATION

To restore a damaged community as quickly as possible, well-prepared reconstruction strategy and available technical guides, both of which need deep and wide discussions among engineers and governmental personnel prior to earthquake, are most essential. *Figure 1* shows an example of reconstruction strategy for earthquake damaged buildings, which is under discussion in Japan. As is shown in the figure, there may be several stages chronologically after the event in general. Although the detailed and practical flow should be determined after further discussions considering wide array of issues related to earthquake disaster planning and social system in each country, local authority and community, temporary restoration of damaged buildings can be the second action to be taken following quick inspections after a major earthquake.

Since the quick inspections are performed within a restricted short period of time, the results may be inevitably coarse. Furthermore, it is not generally easy to identify the residual seismic capacities quantitatively from quick inspections. In the second quasi-stable stage following the emergency stage, damage assessment should be more precisely and quantitatively performed, and then technically and economically sound solutions should be applied to damaged buildings, if restoration is needed. For this end, a technical and quantitative procedure, which is the main objective of the technical guide presented herein, should be well prepared.

The technical guide presented herein mainly focuses on the temporary restoration of RC school buildings for short- to mid-term use, where the seismic capacity of damaged buildings is upgraded to the original capacity before earthquake damage.

OUTLINE OF TECHNICAL GUIDE FOR TEMPORARY RESTORATION

(1) General Flow of Temporary Restoration Strategy

The Technical Guide (AIJ, 1999) for temporary restoration of damaged school buildings proposed by the second AIJ team consists of the following chapters:

- 1. Scope and Objectives of the Temporary Restoration of Damaged Buildings
- 2. Damage Assessment
- 3. Simplified Procedure for Seismic Capacity Evaluation of Original and Damaged Buildings
- 4. Temporary Restoration Instructions
- 5. Application Example

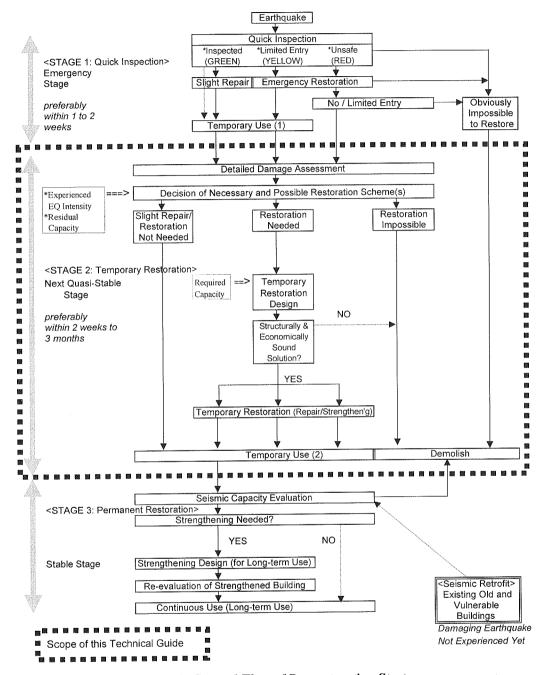

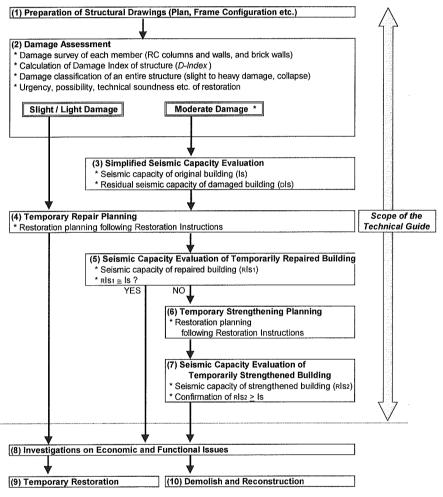

Figure 1: General Flow of Reconstruction Strategy

While discussing on the structural restoration of damaged buildings, damage to both foundation structures and superstructures must be carefully examined and available restoration techniques should be applied to each structure. However, restoration of foundation structures is in general rather costly and the variety of available techniques and solutions can be much wider than superstructures. Note that the Guide is therefore focusing on the temporary restoration techniques of superstructures.

Figure 2 shows a general flow of the temporary restoration of damaged buildings described in the Technical Guide. In the Guide, key words which are essential to understand the concept of the temporary restoration are also defined. Definitions of several essential key words are described below. In Figure 3 are illustrated the basic concepts of the key words.

^{*} The Technical Guide recommends not to use heavily damaged buildings even when they are temporarily upgraded to the original seismic capacity.

Figure 2: General Flow of Temporary Restoration of Damaged Buildings

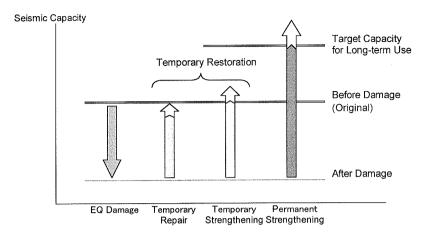

Figure 3: Basic Concept on Temporary Repair, Temporary Strengthening and Permanent Strengthening

Temporary restoration defines actions to damaged buildings and their surrounding environment to ensure and upgrade structural safety and function for short- to midterm use, which are temporarily carried out for several months to around one year until their demolition or permanent restoration. It is further subdivided into temporary repair and temporary strengthening depending on the level of restoration. In this Technical Guide, it is fundamentally aiming to recover the original seismic capacity of members and/or an entire structure.

Permanent restoration defines actions to damaged buildings and their surrounding environment to ensure and upgrade structural safety and function for long-term use. For this purpose, the damaged buildings should be retrofitted against a future major earthquake in addition to aftershocks.

Temporary repair defines actions to damaged members and/or subassemblage to upgrade their structural capacity. It includes repair of cracked members using epoxy resin etc., which is focusing on the recovery of their original capacity. It should be noted that their seismic capacity may not be fully recovered only by temporary repair when they are heavily damaged, and strengthening may be needed in some cases.

Temporary strengthening defines actions to damaged members and/or subassemblage to upgrade their structural capacity to the level of or higher than the original. It includes steel or RC jacketing techniques of temporarily repaired columns, installation of additional structural members such as RC walls, steel braces etc. Seismic capacity of temporarily strengthened members and/or subassemblage need to be confirmed through technical evaluation based on related technical guides, if their capacity higher than the original is taken into account in evaluating their improved capacity.

In the following sections, basic concept and procedures described in chapters 1 through 4 will be briefly presented. An application example will be discussed elsewhere.

(2) Damage Assessment

To seek possible restoration teahniques, quantitative damage assessment of the target building is first needed. In the Guide, a check sheet for damage assessment is proposed as shown in *Table 1*, which is essentially based on the Japanese Standard for Damage Level Classification (JBDPA, 1991). *Table 1* containes following items:

1. General discription of building		
1.1 building name, 1.2 address, 1.6 structu	iral type, 1.9 number of stories	s, 1.14 construction year etc.
2. Damage to building		
2.1 Settlement of building (S m) [Damage		
□None (S=0) □Light (0 <s≤0.2m)< p=""></s≤0.2m)<>	□Moderate (0.2m <s≤1m)< td=""><td>□Heavy (1m<s)< td=""></s)<></td></s≤1m)<>	□Heavy (1m <s)< td=""></s)<>
2.2 Tilting of building (θ rad.) [Damage	Level Classification (2)]	·
\square None (θ =0) \square Light ($0 < \theta \le 0.01$)	☐Moderate (0.01< <i>θ</i> ≤0.03)	□Heavy (0.03< <i>θ</i> ≤0.06)
• • •		□Collapse (0.06< <i>θ</i>)
2.3 Damage to RC columns, RC walls and	l brick walls [Damage Level	Classification (3)]
$D = 10 B_1 / A + 26 B_2 / A + 60 B_3 / A +$	$100 B_4 / A + 1000 B_5 / 7A$	•
Bi: number of RC columns categorized	in damage class i ($i = I$ to V)	shown in <i>Figure 4</i> and <i>Table 2</i>
A: number of inspected members in each	ch story	
\square None ($D=0$) $\stackrel{\frown}{\square}$ Slight ($0 < D \le 5$)		☐Moderate (10< <i>D</i> ≤50)
, , ,	☐Heavy (50< <i>D</i>)	□Collapse (D5=50)
3. Other damage observed		
Falling/overturning hazards such as penth	ouse, exterior stairways, etc.	
4. Damage class of entire building		
Judgement from maximum damage obse	rved in questions 2.1 through 2	2.3 above.
□None □Slight □Light	□Moderate □Heavy	□Collapse
5. Sketches and comments		

As was often observed in RC buildings damaged during 921 Taiwan Chichi Earthquake, brick walls which are widely used but generally considered non-structural members in structural design calculations often had severe damage, and their restoration was therefore identified a major concern in the temporary restoration. Since the original Japanese Standard for Damage Classification does not include damage assessment of brick walls, their damage survey is added in the check sheet. Damage definitions of RC members and brick walls, and their sample photos are shown in *Figure 4* and *Table 2*, respectively. It should be also noted that discussion results with researchers and engineers in Taiwan are incorporated in defining brick wall's damage shown in *Figure 4* and *Table 2*.

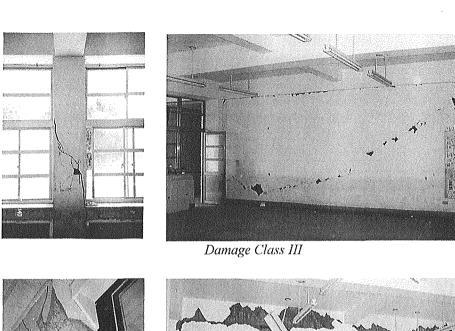

Damage to brick walls should be considered to categorize the damage level of an entire structure. However, since the original formulations for damage index D (JBDPA, 1991) to define the damage level of an entire structure is based only on RC column damage to simplify calculations, damage to brick and RC walls are provisionally neglected in the damage level classification as shown in 2.3(6) of *Table 1* and the definition of *D-Index* described in the above box, while their contribution to the seismic capacity of an entire structure, as will be discussed later, is taken into account. It should be therefore noted that a more rational formulation to represent damage level needs to be developed in the future considering contribution of wall damage to entire damage category through further discussions and calibrations.

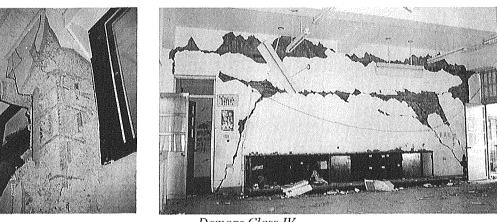

^{*} Items listed above correspond to those shown in Table 1.

Damage Class IV

Damage Class V
Figure 4: Damage Example Photos (left: RC columns / right: brick walls)

Table 2: Definition of Damage Class

(a) RC columns and walls

Damage Class	Description of Damage			
I	- Visible narrow cracks on concrete surface (Crack width is less than 0.2 mm)			
II	- Visible clear cracks on concrete surface (Crack width is about 0.2 -1.0 mm)			
ш	- Local crush of covering concrete			
Ш	- Remarkable wide cracks (Crack width is about 1.0 - 2.0 mm)			
137	- Remarkable crush of concrete with exposed reinforcing bars			
IV	- Spalling off of covering concrete (Crack width is more than 2.0 mm)			
	- Buckling of reinforcing bars			
7.7	- Cracks in core concrete			
Y	- Visible vertical deformation in columns and/or walls			
	- Visible settlement and/or inclination of the building			

(b) Brick walls

Damage Class	Description of Damage
I	- Visible narrow cracks at interfaces between brick walls and boundary RC members (i.e., columns or beams)
П	 Visible clear cracks at interfaces between brick walls and boundary RC members (i.e., columns or beams), but slight shear cracks and/or spalling of finishing at corner(s) on brick wall
Ш	- Clear shear cracks and/or slippage of brick wall, and spalling of finishing
IV	- Extensive shear cracks, slippage and/or spalling of finishing - Spalling of some bricks
V	- Massive spalling of bricks - Out-of-plane deformation of brick wall

(3) Seismic Capacity Evaluation

Seismic capacity index Is is defined by Eq. (1). Although the basic concept is essentially based on the Japanese Standard for Seismic Capacity Evaluation (JBDPA, 1990), a calculation procedure is simplified and modified from the observed evidence of damaged buildings, i.e., (a) most of the damaged buildings failed in a brittle manner and (b) brick walls highly contributed to the overall structural performance. Member ductility is therefore neglected in the Guide while sectional properties such as re-bar arrangement, sectional size, material strength etc. are taken into account in calculating shear and flexural strengths of columns. Furthermore, the contribution of wall strength to overall lateral resistance of a building is considered through its sectional area A_W and the ultimate shear stress τ_{W} . Figure 5 illustrates definitions of typical brick wall types and their ultimate shear stress τ_{DW} , where the values of τ_{DW} are determined considering the past experimental results carried out in Taiwan.

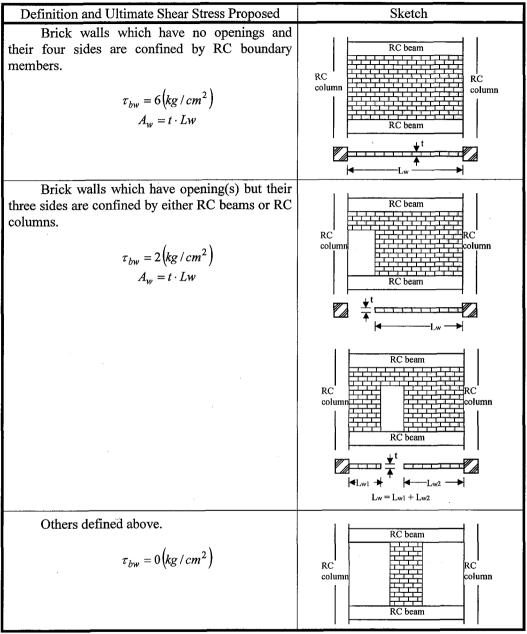

Figure 5: Definitions of Brick Wall Types and Their Ultimate Shear Stress

$$Is = Eo \times SD \times T \tag{1}$$

where, Eo: Basic structural index, estimated by Strength Index (C), Ductility index (F), and Story Index (n+1)/(n+i) at each story and each direction when the story or building reaches at the ultimate limit state due to lateral force. In the Guide, Eo is defined as the larger value of the following Eqs. (2) and (3).

$$E_0 = \frac{n+1}{n+i} \{ (C_{sc} + C_{bw}) + 0.7(C_c + C_w) \} \times F_1$$
 (2)

$$E_0 = \frac{n+1}{n+i} (C_c + C_w) \times F_2 \tag{3}$$

n: Number of stories.

i : Story level concerned.

Csc: Shear coefficient of short columns.

 C_c : Shear coefficient of columns other than short columns.

 C_w : Shear coefficient of RC walls.

Chw: Shear coefficient of brick walls.

 C_i (i=sc, c, w or bw) is calculated from the following equation.

 $C_i = \Sigma[\text{lateral resistance of member } j \text{ in } i\text{-th story}]/[\text{weight of building above}]$

 F_1 : Ductility index of short columns and brick walls. (=0.8)

 F_2 : Ductility index of columns and RC walls. (=1.0)

SD: Modification factor, estimated by stiffness discontinuity along stories, eccentric distribution of stiffness in planes, irregularity of framing, etc. In the Guide, SD index of a building is simply defined as SD = SD1 * SD2, where SD1 = 0.9 when it has plan irregularity and SD2 = 0.9 when it has elevation irregularity.

Reduction factor, estimated by the grade of deterioration. Considering that
the Guide aims to upgrade the damaged building to the original capacity, T
is simply assumed 1.0.

To discuss necessary actions to damaged buildings, the relationship between their original and residual capacity can be most informative. To estimate the residual seismic capacity of damaged buildings, capacity reduction factors η corresponding to each damage class of members are proposed in the Guide as shown in **Table 3**. The seismic capacity index of damaged building DIs can be therefore calculated from the original capacity and reduction factors η of each member.

In the Guide, decision criteria for necessary actions are proposed as follows:

- (1) When the seismic capacities of original (*Is*) and damaged buildings (*DIs*) are almost same (*DIs* / $Is \ge 0.95$ is proposed in the Guide), temporary repair is not necessarily required.
- (2) When DIs is lower than Is (DIs / Is < 0.95 is proposed in the Guide), temporary repair is required based on the Instructions for Temporary Restoration which will appear subsequently. The seismic capacity of repaired building (RIsI) is then calculated considering the recovery factors ψ shown in **Table 4**.
- (3) If RISI is still lower than IS (RISI / IS < 0.95), then temporary strengthening is required.

Each technique available for temporary repair and strengthening can be found in the

Table 3: Capacity Reduction Factors η due to Damage

Damage Class	RC Columns/Walls	Brick Walls
I	0.95	0.95
II	0.7	0.7
III	0.3	0.3
IV	0	0
V	0	0

Table 4: Capacity Recovery Factors w after Temporary Repair

Damage Class	RC Columns/Walls	Brick Walls
I	0.95 ⁽¹⁾ - 1.0	$0.95^{(1)} - 1.0$
II	0.95 - 1.0 ⁽²⁾	$0.90 - 1.0^{(2)}$
III	$0.9 - 1.0^{(2)}$	1.0 ⁽³⁾
IV	0.8 - 1.0 ⁽²⁾	1.0 ⁽³⁾
V	$0.7 - 0.9^{(2)}$	$1.0^{(3)}$

In case of (1) no repair, (2) careful design and good workmanship, and (3) reconstruction of brick wall, respectively.

(4) Instructions for Temporary Restoration

In the Technical Guide, approximately 30 restoration techniques are instructed. They include emergency restoration technique and temporary restoration techniques. *Figure 6* shows an example of temporary restoration techniques for RC columns compiled in the Guide.

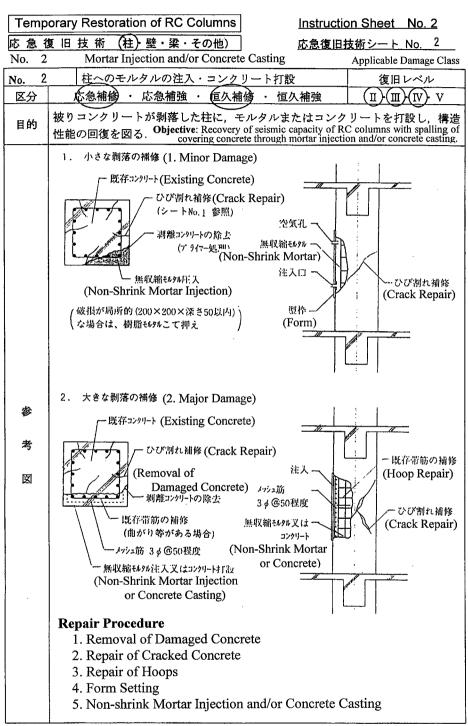

CONCLUDING REMARKS

The AIJ Technical Guide for temporary restoration of RC school buildings damaged due to 921 Taiwan Chichi Earthquake is briefly described. Although the Guide still contains issues which need further investigations and discussions, the author strongly desire that the Guide can lead to a more rational and practical guide for RC buildings through further researches in Taiwan.
